Issues toward helical fusion reactor
- Reduction in ripple loss of helically trapped particle, control of neoclassical transport
- Mitigate anomalous transport

Drift optimization is one of the key subjects
In planner-axis heliotron devices such as LHD, CHS and Heliotron E\(^{[1-3]}\), inwardly-shifted configuration
  => Alignment between drift and flux surfaces
  => Improve neoclassical transport and energetic particle confinement
- Experimentally obtained improvement in the energetic particle confinement
- Reduction in neoclassical transport coefficient. \(^{[4]}\)
- Also preferable energy confinement toward ISS scaling\(^{[5,6]}\)
  => Considered to be one of the candidates to mitigate anomalous transport

In this study, we investigate:

1. Energetic ion transport and its influence on MHD activities
2. Global energy confinement in NBI plasmas of Heliotron J with regard to bumpiness magnetic field component.

**Helical-axis heliotron device Heliotron J**

- Based on omnigeneous optimization scenario.
- Control of the toroidal mirror ratio “bumpiness” is important to reduce ripple loss and neoclassical transport.
- Theoretically predicted importance in experimental study for bumpiness effect

**Favorable bumpy field gives slower orbit loss**

In this study, we investigate:

1. Energetic ion transport and its influence on MHD activities
2. Global energy confinement in NBI plasmas of Heliotron J with regard to bumpiness magnetic field component.
Control of bumpy magnetic field strength (mirror ripple, ε_b) by changing TA and TB coil currents

- High ε_b : Higher mirror ripple
- Low ε_b : Mirror field reversal (at axis)

Constant parameters:
- \( R_{ax}/\langle a_p \rangle = 1.2 \text{ m}/0.17 \text{ m}, V_p \sim 0.7 \text{ m}^3 \)
- Edge rotational transform
- Magnetic well in entire region
Bumpy magnetic field ($\varepsilon_b$) control (2)

Radial profile of field components and iota

Control of bumpiness with keeping $R_{ax}$, $<a>$, edge rotational transform and other main Fourier components (Toroidicity, Helicity)
∇B drift becomes smaller with bumpiness (\(\varepsilon_b\))

- Poloidal profiles of \(|B|\) along a field line (upper) and \(|B|\) contour plots (lower) in Boozer co-ordinate (r/a=0.52)

- In the high \(\varepsilon_b\) case, minimum values of field strength at the ripple bottoms are flattened

- Angle between the field line and \(\nabla B\) becomes relatively acute.
  
  \[\nabla B\text{ drift becomes smaller in the high }\varepsilon_b\text{ configuration.}\]

  \[\implies \text{Difference between flux surface and drift orbits by }\nabla B\text{ drift becomes smaller in the high }\varepsilon_b\text{ configuration.}\]

- In low \(\varepsilon_b\) case, the strength of the ripple bottoms varies along field line

\[\varepsilon_b = 0.15 \text{ (High)} \quad 0.06 \text{ (STD config.)} \quad 0.01 \text{ (Low)}\]
1/e decay time of energetic CX flux becomes longer with $\varepsilon_b$ *

- Decay of CX flux after NBI turn-off in ECH sustained plasmas, $(E_{NB}=28\text{kV} \& \langle \lambda_{\text{NBI}} \rangle \approx 155^\circ \text{ deg.})$
  $(E_{CX}=18\text{kV}, \lambda_{\text{pitch}} \approx 130^\circ \Rightarrow \text{passing})$
- $n_e=0.8 \times 10^{19} \text{m}^{-3}$

$\Rightarrow$ 1/e decay time becomes longer as bumpiness increased

- Under the experimental condition, slowing-down time and CX loss time are expected to be unchanged in the experiments.
- Time evolution of loss rate by orbit calculation at $E = 18\text{keV} \& \rho = 0.25$
- Slower grad-$B$ drift with increasing $\varepsilon_b$
Longer effective loss-time in high-εb configuration

- The energy spectrum is calculated using Fokker-Planck equation for ion.++
- The observation result can be interpreted with FP analysis by taking effective loss time into account.

++ R.H.Flowler et al. ORNL/TM-5487 (1976)

- Effective loss time in the high-εb configuration is longer than the others. => These results revealed that effectiveness of εb to energetic particle confinement

Observation of bursting GAE in high $\varepsilon_b$ configuration

- Bursting GAEs ($m \sim 4/n = 2, f_{\text{exp}} = 40 \sim 70 \text{ kHz}$) with rapid frequency chirping.
- Some plasma parameters such as $H_\alpha$ and $T_e$ (SX foil) are simultaneously modulated with the bursting GAEs.

$\Rightarrow$ indicates that GAE would affect energetic ion transport.

most unstable mode when fast ion pressure becomes fairly high.

- GAEs have been observed at several magnetic configurations in NBI plasmas of Heliotron J, however, strong bursting GAE is observed in high $\varepsilon_b$ configuration.

Hybrid Directional Langmuir Probe (HDLP) installed in Heliotron J*

- Hybrid Directional Langmuir probe (HDLP) system is installed into Heliotron J. (under collaboration research with Dr. Nagaoka NIFS)
- Can measure Co-going and CTR-going ion fluxes separately.

**Targets**
- Core plasma (Te, ne, potential)
- Fast ion flux
- Plasma flow
- Heat flux
- Magnetic fluctuation

**Advantage**
- High heat resistance
- High spatial resolution ~4mm
- High time resolution ~1μsec

**Disadvantage**
- Energy spectrum (NPA, LIP)
- Pitch angle resolution (LIP)

The combination of other fast ion diagnostics is important.
Fast Ion Response to bursting GAE

- Bursting GAE occurs in NB and EC heated plasma.
- The frequency of GAE chirps down quickly.
- The Co-directed ion flux synchronized with GAE burst is observed and it is sensitive to the burst interval and amplitude.
- The CTR-going ion flux is not response to GAE burst.
  => Considered as a resonant convective oscillation
- Influence of GAE on the energetic ion confinement should be taken into account for further optimization of the helical-axis heliotron configuration.

Typical time evolution of NBI sustained plasma

- CTR injection plasma ($P_{INJ} = 550\text{~to~}560\text{~kW}$) (Initial plasma is produced by ECH)
- Density control by gas puffing ($\sim 2 \times 10^{19} \text{~m}^{-3}$)
- CTR direction $I_p$ (BS;Co, NBCD;CTR) (reduce rotational transform)
Calculation of beam absorption profile*

1. HFREYA : beam birthpoints calculation using Monte-Carlo method
2. mcnbi : calculation code for estimation of re-distribution of fast ion
3. FIT : beam absorption profile calculation using Fokker-Planck equation

- Modified HFREYA to apply 3D shape of plasma & inner vacuum vessel of Heliotron J.
- Calculation of ion orbit without slowing down process at the initial energy of beam ions.
  =&gt; Do not treat the orbit loss of fast ions including slowing down processes
- The slowing down process of fast ions and the energy transfer to both the bulk electrons and ions are calculated by the Fokker-Planck analysis including CX loss of fast ions.

Estimation of beam absorption under assumption of..
- Parabolic density profile
  (line-averaged n_e \sim 1\times10^{19} \text{ to } 3\times10^{19} \text{ m}^{-3})
- Parabolic T_e (T_i) profiles with core temperature of 400 eV (300 eV).
- Z_{\text{eff}} = 1
- Edge neutral density of 2\times10^{16}\text{ m}^{-3}

Neutral density profile will be estimated using H\alpha/D\alpha measurement and Monte-Carlo simulation.

Absorption rate of around 35% for three \epsilon_b cases
Preferable energy confinement in both high and medium $\varepsilon_b$

**Dependence of stored energy (left) and energy confinement time (right) on $P_{NB}$**

- Power scan experiments at constant density ($2 \times 10^{19} \text{m}^{-3}$) for three $\varepsilon_b$ configurations. ($200 \text{kW} < P_{NB} < 600 \text{ kW}$)
- Evaluation of $W_{dia}$ by diamagnetic loop data.
- $W_{dia}$ in the high- and medium-$\varepsilon_b$ configurations is clearly higher than that in the low-$\varepsilon_b$ case.
- The difference of $W_{dia}$ between the high- and medium-$\varepsilon_b$ configurations is small, but $W_{dia}$ in high-$\varepsilon_b$ case is more than 5% higher than that of the medium- $\varepsilon_b$ configuration.
- Preferable energy confinement for high and medium $\varepsilon_b$ configurations
Increase in temperature in high and medium $\varepsilon_b$ configs

- Weak dependence of bulk ion temperature (deuterium) by CX-NPA on NB power, however, slightly increase in $T_i$ with $\varepsilon_b$
- Intensities of electron cyclotron emission ($I_{ECE}$) at the core region increase with $P_{NB}$ (ECE data has not been calibrated absolutely)
- Higher in high and medium $\varepsilon_b$
  ➔ Increase in electron temperature for the high and medium $\varepsilon_b$ configs.

$T_i$ and $I_{ECE}$ vs. $P_{NB}$
Comparison with ISS95 scaling

- Comparison of energy confinement time $\tau_E^{\text{DIA}}$ with International Stellarator Scaling ($\tau_E^{\text{ISS95}}$)
- Enhancement factor ($H_{\text{ISS95}} = \tau_E^{\text{DIA}} / \tau_E^{\text{ISS95}}$) around 1.8 and 1.7 for high and medium $\varepsilon_b$ cases, respectively, which is higher than the low $\varepsilon_b$ condition around 1.4.

- Power dependence is similar to ISS scaling.

ISS95 scaling law

$$\tau_E^{\text{ISS95}} = 0.079 P^{-0.59} n_e^{0.51} B^{0.83} R^{0.65} a_p^{2.21} \sqrt[2/3]{2/\pi} \left(2/3a\right)^{0.4} P_{\text{abs}}$$
Summary

We investigated energetic particle and global energy confinement in NBI plasmas of Heliotron J, focusing on the bumpiness effect, being key factor for drift-optimization in helical-axis heliotron configuration of Heliotron J.

- 1/e decay time of high energy CX flux became better with increasing bumpiness, which shows bumpiness is effective to control of the energetic particle confinement.
- Co-going lost ion flux synchronized with bursting GAE can be measured with hybrid directional Langmuir probe (HDLP) system installed in Heliotron J. Influence of GAE on the energetic ion confinement should be taken into account for further optimization of helical-axis heliotron configuration.
- In the power scan experiment at a constant density condition, the good enhancement factor of the energy confinement time ($H_{1SS95}$) was obtained in high and medium-$\varepsilon_b$ configurations.
- Bumpiness control experiments revealed the effectiveness of the control of bumpiness on the confinement both for the energetic particle and the bulk plasmas.

- Further experiment and analysis are needed to clarify the relation between bumpiness effect and anomalous transport with attention to turbulence, plasma flow, rotation and radial electric field.
