

## §22. Study on MHD Wall Shear Turbulent Flow with Buoyancy Effect

Satake, S. (Tokyo Univ. of Science),  
Kunugi, T. (Kyoto Univ.)

### 1. Objectives

Liquid-metals as coolant material in a fusion reactor have a significant role in the design of advanced reactors. To understand it better, investigation of thermal behavior under a magnetic field is needed, such as in the case of low Prandtl (Pr) number fluid flow with buoyancy effect. In the present study, direct numerical simulations (DNS) for low Pr number fluid flow of turbulent heat transfer with buoyancy effect has been carried out under a magnetic field. In this simulation the values of Hartmann number  $Ha$  were kept as 0 and 6, and Prandtl number was 0.06. Grashof numbers were  $4.8 \times 10^6$ . Using DNS the parameter such as mean temperature, turbulent heat flux, and temperature variant were quantified. The Reynolds number for channel flow based on friction velocity, viscosity, and channel half width was set to be constant as  $Re_\tau = 150$ . A uniform magnetic field was applied in a direction perpendicular to the wall of the channel. Using the simulation we could see that with an increase in heat transfer, thermal plume by the effect of buoyancy filled the entire region of the channel. In case of an applied magnetic field, it was seen that the turbulence became weak with the magnetic field, although the thermal transport was also increased by the buoyancy effect of the thermal plume.

### 2. Numerical method for direct numerical simulations

In our simulation model a uniform magnetic field  $B_0$  defines the y-axis perpendicular to the streamwise direction that defines the x-axis as shown in Fig. 1. Our DNS code is a hybrid of spectral finite difference method. And for the normalization of the temperature equation, a constant positive temperature difference between the bottom and top walls was used. The gravitational acceleration in the y-direction gives rise to an unstable buoyancy effect. Furthermore, the wall normal component imposes the additional body force according to Bossinestq-approximation. The Grashof number was varied as shown in table 1. All variables and parameter in the governing equations were normalized by the channel half-width, the friction velocity and. The Reynolds number was kept fixed at 150; the number was based the friction velocity and channel half width. The fluid then flowed with a constant pressure. The Neumann condition for the electrical potential was adopted at the wall which meant the existence of an insulation was assumed here. The Hartmann numbers were set to be 0 and 6. These numbers were based on the values of the magnetic field, the kinematic viscosity, the electrical conductivity and the channel half-width. Table 1 summarizes the values of Prandtl number, Reynolds number, and Hartmann number. Periodic boundary conditions were applied to the

streamwise (x) and spanwise (z) directions. For the wall-normal direction (y), a non-uniform mesh spacing was employed that was specified by a hyperbolic tangent function. A non-slip condition at the wall was applied to the velocity components. The Prandtl number was 0.06 as is for Lithium, and this number was selected for the working fluid used for this computation.

Table 1 Computational parameters

$Re_\tau$	Pr	Ha	Gr	Region	Grid number	$\Delta x^+$	$\Delta y^+$	$\Delta z^+$
150	0.059	0	$4.8 \times 10^6$	$5\pi\delta \times 2\delta \times 2\pi\delta$	128x128x128	16.8	0.16-4.2	8.9
150	0.059	6	$4.8 \times 10^6$	$5\pi\delta \times 2\delta \times 2\pi\delta$	128x128x128	16.8	0.16-4.2	8.9

### 3. Results

Streaky structures are shown in Fig. 2. With buoyancy effect and magnetic field, many structures exist near both walls. Moreover, the structures have a meandering appearance. The structures with buoyancy effect are merged, become mainly two scales. The motion is attached from the one side wall to the opposite side wall. This phenomenon is known as thermal plume. Even in the case of applied magnetic field, the high thermal heat transfer still remains owing to the thermal plume.
